version: 779109-40323 13:00

- Finding a pattern in a larger text is a common problem in many applications
- Typical example is searching in a text editor or word processor
- There are many more:
 - DNA sequencing / bioinformatics
 - Plagiarism detection
 - Search engines / information retrieval
 - Spell checking
 - ...

Introduction/invitation Brute-force Boyer-Moore FWA KMP Robin-Karp

Types of problems

- The efficiency and usability of algorithms depend on some properties of the problem
- Typical applications are based on finding multiple occurrences of a single pattern in a text, where the pattern is much shorter than the text
- The efficiency of the algorithms may depend on the
 - relative size of the patterns
 - expected number of repetitions
 - size of the alphabet
 - whether the pattern is used once or many times
- Another related problem is searching for multiple patterns at once
- In some cases, fuzzy / approximate search may be required
- In some applications, preprocessing (indexing) the text to be searched may be beneficial

Problem definition and some terminology

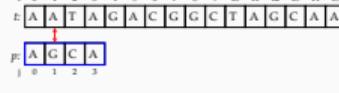

- We want to find all occurrences of pattern p (length m) in text t (length n)
- The characters in both t and p are from an alphabet Σ , in the example $\Sigma = \{A, C, G, T\}$
- The size of the alphabet (q) is often an important factor
- p occurs in t with shift s if $t[0:m] \cdots t[s+m]$, we have a match at $s = 3$ in the example
- A string x is a prefix of string y , if $y = wx$ for a possibly empty string w
- A string x is a suffix of string y , if $y = wx$ for a possibly empty string w

Brute-force approach: worst case**Brute-force approach: worst case****Brute-force approach: worst case****Boyer-Moore algorithm**

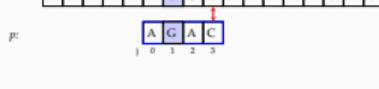

slightly simplified version

- The main idea is to start comparing from the end of p
- If $t[i]$ does not occur in p, shift m steps
- Otherwise, align the last occurrence of $t[i]$ in p with $t[i]$

Boyer-Moore algorithm

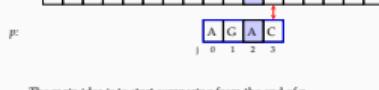

slightly simplified version

- The main idea is to start comparing from the end of p

- If $t[i]$ does not occur in p, shift m steps
- Otherwise, align the last occurrence of $t[i]$ in p with $t[i]$

Brute-force approach: worst case**Brute-force approach: worst case**

- Worst-case complexity of the method is $O(nm)$
- Crucially, most of the comparisons are redundant
 - for $i > 0$ and any comparison with $j = 0, 1, 2$, we already inspected corresponding i values
- The main idea for more advanced algorithms is to avoid this unnecessary comparisons with the help of additional pre-processing and memory

Boyer-Moore algorithm

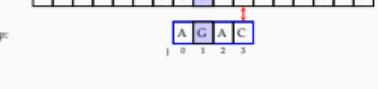

slightly simplified version

- The main idea is to start comparing from the end of p
- If $t[i]$ does not occur in p, shift m steps
- Otherwise, align the last occurrence of $t[i]$ in p with $t[i]$

Boyer-Moore algorithm

implementation and analysis

```
last = []
for j in range(m):
    last.append(t[j] == p[j] - 1)
i, m = 0, m - 1
while i < n:
    if t[i] == p[j]:
        if j == 0:
            return i
        else:
            i -= 1
            j -= 1
    else:
        k = last.get(t[i], -1)
        i += m - min(j, k+1)
        j = m - 1
return None
```

A quick introduction to FSA

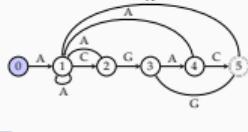

- Another efficient way to search a string is building a finite state automaton for the pattern
- An FSA is a directed graph where edges have labels
- One of the states is the *initial state*
- Some states are accepting states
- We will study FSA more in-depth soon

KMP algorithm

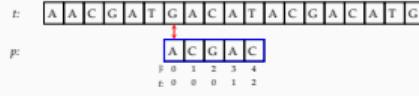

demonstration

- In case of a match, increment both i and j
- On failure, or at the end of the pattern, decide which new $p[j]$ compare with $t[i]$ based on a function f
- $f[j] - 1$ tells which j value to resume the comparisons from

KMP algorithm

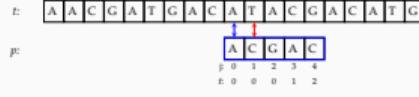

demonstration

- In case of a match, increment both i and j
- On failure, or at the end of the pattern, decide which new $p[j]$ compare with $t[i]$ based on a function f
- $f[j] - 1$ tells which j value to resume the comparisons from

KMP algorithm

demonstration

- In case of a match, increment both i and j
- On failure, or at the end of the pattern, decide which new $p[j]$ compare with $t[i]$ based on a function f
- $f[j] - 1$ tells which j value to resume the comparisons from

KMP algorithm

demonstration

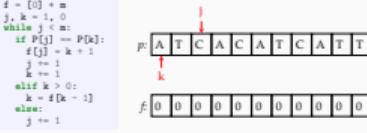

- In case of a match, increment both i and j
- On failure, or at the end of the pattern, decide which new $p[j]$ compare with $t[i]$ based on a function f
- $f[j] - 1$ tells which j value to resume the comparisons from

Complexity of the KMP algorithm

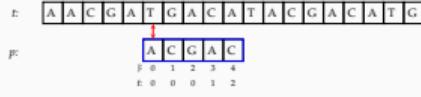

```
i, j = 0, 0
while i < n:
    while i <= m:
        if T[i] == P[j]:
            if j == m - 1:
                return i
            else:
                i += 1
                j += 1
        elif j > 0:
            j = f[j] - 1
        else:
            i += 1
    return None
```

- In the while loop, we either increase i, or shift the comparison

- As a result, the loop runs at most $2n$ times, complexity is $O(n)$

Building the prefix/failure table**KMP algorithm**

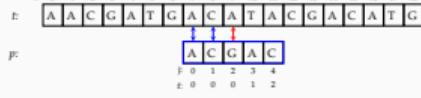

demonstration

- In case of a match, increment both i and j
- On failure, or at the end of the pattern, decide which new $p[j]$ compare with $t[i]$ based on a function f
- $f[j] - 1$ tells which j value to resume the comparisons from

        else:
            j += 1
```

Rabin-Karp algorithm

- Rabin-Karp string matching algorithm is another interesting algorithm
- The idea is instead of matching the string itself, matching the hash of it (based on a hash function)
- If a match found, we need to verify – the match may be because of a hash collision
- Otherwise, the algorithm makes a single comparison for each position in the text
- However, a hash should be computed for each position (with size m)
- Rolling hash functions avoid this complication

Rabin-Karp string matching

demonstration with additive hashing

Building the prefix/failure table

another example

```
f = [0] * m
```

```
j, k = 1, 0
```

```
while j <= m:
```

```
    if P[j] == P[k]:
```

```
        f[j] = k + 1
```

```
        j += 1
```

```
    k += 1
```

```
    elif k > 0:
```

```
        k = f[k - 1]
```

```
    else:
```

```
        j += 1
```
